

Possible impact of hydrological data on frequency response

Slaven Kincic, PNNL slaven.kincic@pnnl.gov Modeling Validation Subcommittee Meeting, January 24-26th 2024

PNNL is operated by Battelle for the U.S. Department of Energy

Problem Statement

Hydro generation not adequately and inaccurately represented in planning and operation studies:

- Water availability not updated seasonally or modeled in basecases •
- No interdependencies between resources, environmental constraints ignored

The six-turbine Edward Hyatt Power Plant was taken offline after the water level in the Oroville Dam reservoir that feeds it sank to an historic low

As the river's biggest reservoirs, Lakes Powell and Mead, fall to one-third of their capacity, the dwindling flow threatens electricity generation.

U.S. DEPARTMENT OF ENERGY

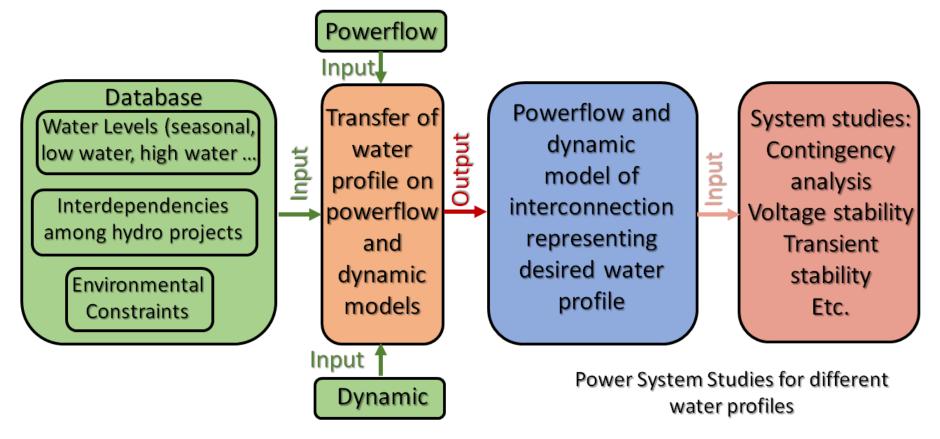

The software will update the existing steady state and dynamic model based on desired historical hydro conditions, allow modification while respecting interdependences and impose desired hydro profile, including dispatch constraints on hydro plants, as illustrated in Figure below:

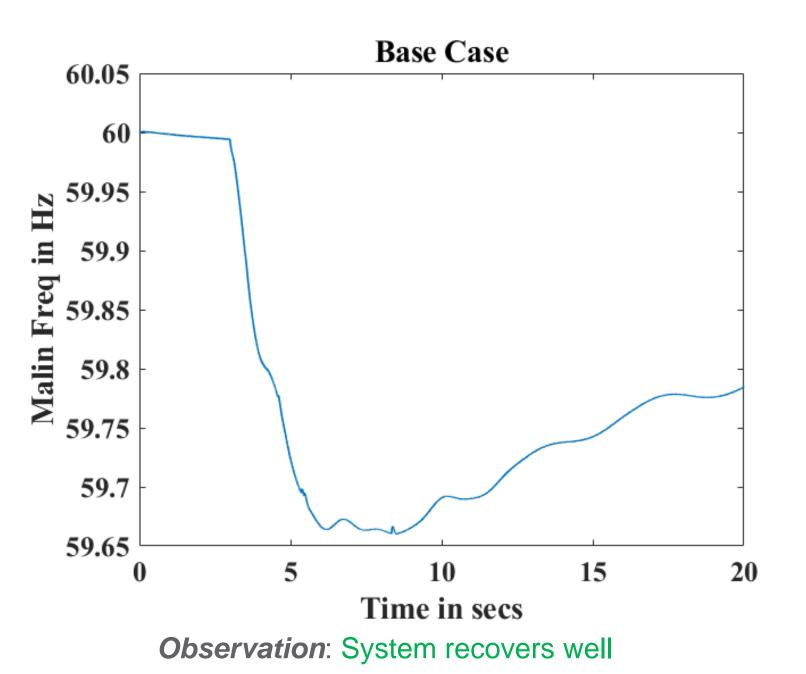

- 2022 Light Spring Case has been used as the base case
- Four scenarios have been simulated:
 - Scenario1: 'Base Case'
 - Scenario2: 'Only Wind Curtailment'
 - Scenario3: 'Only Hydro Update'
 - Scenario4: 'Wind Curtailment + Hydro update'
- Governor powerflow option in PSLF has been used to redispatch the changes in the generation made in the different scenarios considered using other resources throughout the system
- 'N-2' Palo Verde Trip Event has been simulated
- Wind units has been curtailed in the NORTHWEST area

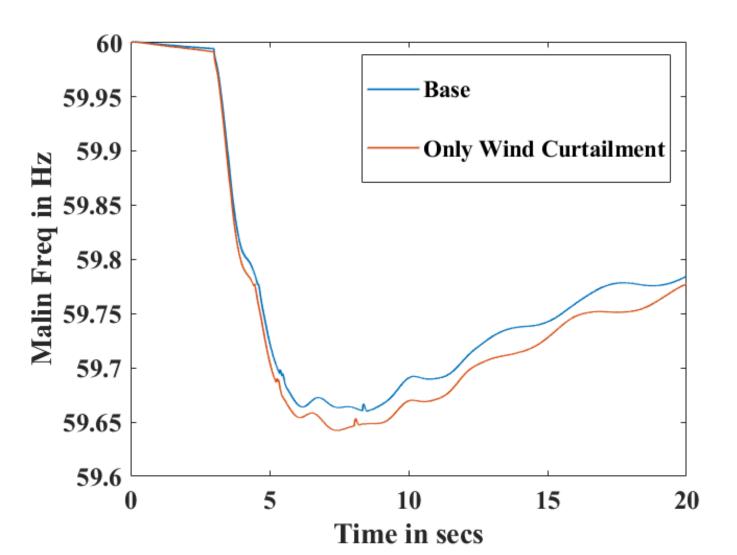

- ٠ have been curtailed
- Wind units are only tripped in the • Northwest area (~1500 MW)
- curtailed.

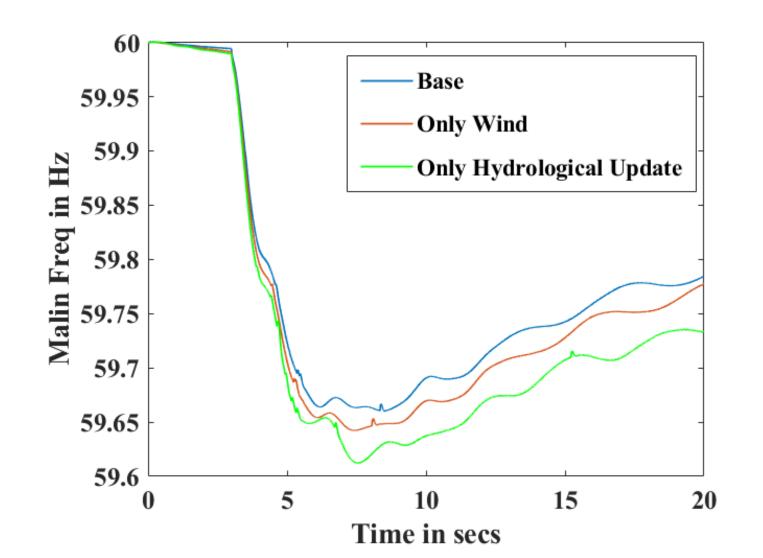

20% of the total wind generation in the Northwest and California areas

The hydro units whose generation data needs to be updated based on the new hydrological data are not utilized in the governor powerflow dispatch when wind generation is

- curtailed
- updated.
 - 1 pu).

Observation: System recovers well similar to base case but has slightly lower nadir and much slower recovery rate compared to Scenario 1 and Scenario 2

No wind generation has been

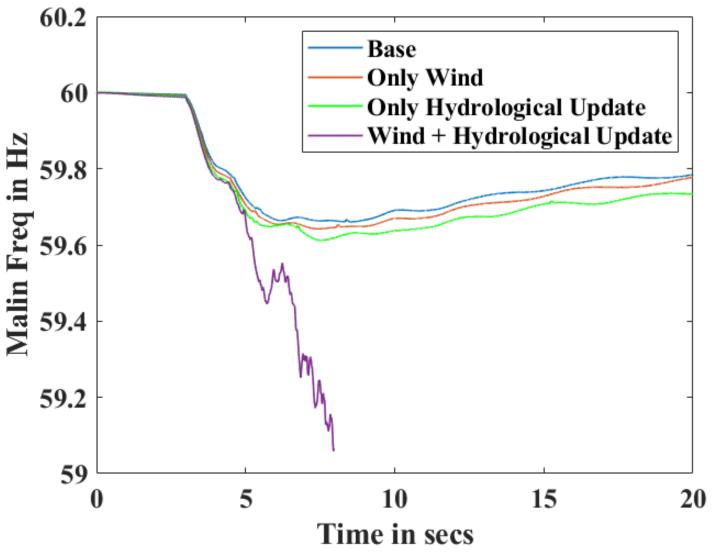

The Pgen, Pmin and Pmax of the hydrounits have been

updated based on the new hydrological data. Total of 4720 MW have been

'Head' value in the corresponding dynamic governor models has been updated to 0.75 pu (default is

• Scenario

It should be noted that these simulations have also been redone by implementing the governor powerflow redispatch considering only units whose baseload flag value is 0. Noticed almost same behavior, in the results, as shown before without considering baseload flag constraint.

Observation: System doesn't recover which clearly shows the importance of having an accurate reflection of the hydro units generation based on the hydrological data

Updates made in both Scenario 2 and Scenario 3 have been made in this

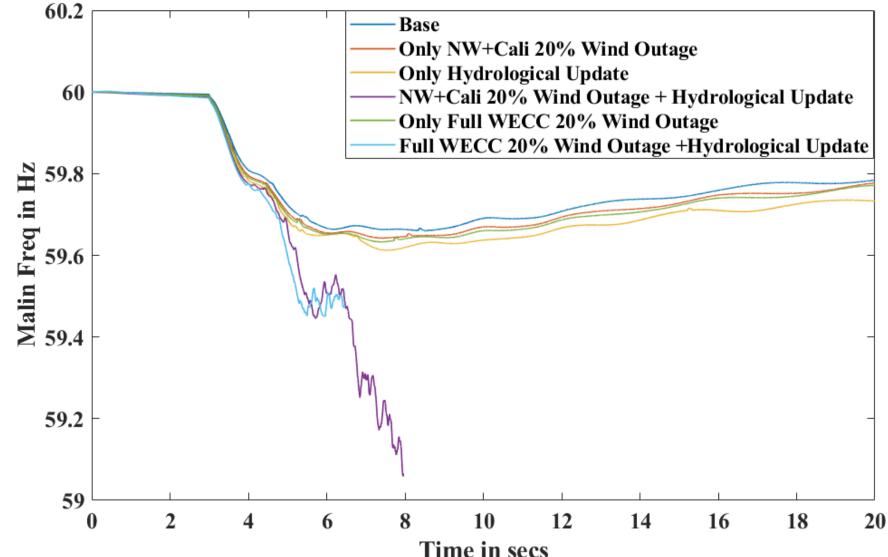

Wind Curtailment Cases Considering Full WECC

- Total wind generation of 10.52 GW is observed in the whole of WECC in the base case.
- 20% (2104 MW) of this total wind generation has been curtailed and has been re-dispatched via other sources in the system (except the hydro units in which hydrological update is to be made) using governor powerflow approach.
- Not significant difference in the system response has been observed when compared to Scenario 2 and Scenario 4 (when 20%) wind is curtailed based on the total wind generation in only Northwest and Southern California areas).

Scenario 6: Result Comparison (20% Wind Curtailment based on Full WECC wind generation + Hydrological update) with Scenarios 1-5

Observation: System response in this scenario is very similar (does not recover) to Scenario 4 (20% wind outage based on NW & Southern Cali wind generation areas + hydrological update)
